part is an ionization fission chamber. The pulses generated in both canals of the chamber reach, via the amplifiers I and III, the double-coincidence circuit II (time resolution  $0.5 \mu\text{sec}$ ). The pulses are counted in IV by a mechanical counting device. The fission chamber is brass filled with argon and sealed hermetically. It contains the following: 1) a  $\text{U}_3\text{O}_8$  preparation ( $90\% \text{U}^{235}$ ,  $\sim 0.1 \text{ mg/cm}^2$ ) upon an Al foil ( $0.4 \text{ mg/cm}^2$ ), 2) collimators, 3) a set of differently thick foils of the metal to be examined, 4) collector electrodes. Collimator thickness and argon pressure ( $\sim 100 \text{ mm Hg}$ ) were chosen so as to keep the fragment energy losses in the collimator negligibly low. This arrangement excludes counting of spurious pulses (from  $\gamma$ -quanta or recoil nuclei); all measurements may be carried out at the reactor at a thermal neutron flux of between  $10^6$  and  $10^8 \text{ n/cm}^2 \text{ sec}$ . In order to illustrate the operation of the device, the determination of the ranges and specific energy losses for fragments with equal range is discussed. Zero thickness of the material in which the range is to be examined gives rise to  $N_0$  coinciding pulses. The number of coincidences decreases if  $d$  rises for the same amount in each of the channels. At a certain  $d = d_c$ , the num-

ber of coincidences becomes zero or drops to a minute fraction ( $\ll$ ) of  $N_0$ , according to the sensitivity of the detector; thus,  $d_c$  characterizes the range of the fragments. The specific energy losses are determined as follows: Foil sets with  $d = d_c$  of a material whose range dependence of the specific losses is known are inserted into both canals. Then, in one canal all foils, one after the other, are replaced by foils of the material to be examined; on this occasion, these foils must have such a thickness that the number of pulses does not vary on exchange. In this way the specific energy losses can be determined for all ranges. Range and specific energy loss of heavy and light fragments may be determined separately, too. For this purpose,  $N_0$  is determined as before, then the foils to be investigated are successively removed from one canal until the number of coincidences becomes small with respect to  $N_0$ . By this processing, the fragments of maximum range are separated. Then, the foils from the second canal are successively removed until the number of coincidences is equal to zero. The number of foils in the second canal now characterizes the range of the heavy fragments. The energy losses are determined analogously. Finally, the yield-to-range curves for Au and Al as determined by this method are compared

TITLE: Determination of the sublimation energy of the system  
Pd-H by a pulse method

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, v. 4, no. 9, 1961, 102-103

TEXT: The authors determined the integral sublimation energy of the system Pd-H. For this purpose, they developed a pulse method which relies on the determination of the energy limit of the current interruption that is caused by pulse heating. That means that the minimum energy required for a complete evaporation of the test specimen is to be determined. The experimental arrangement was described in a previous paper of the authors ("Pribory i tekhnika eksperimenta", no. 1, 85, 1960). In order to ensure the necessary current-pulse duration in the discharge circuit of the arrangement, an additional coil having an inductance of  $1.4\mu h$  was used. With the aid of such an arrangement, it is possible to heat a palladium specimen electrolytically saturated with hydrogen when sending a current

Determination of the sublimation...

pulse through it. The sublimation energy is calculated from the time of current interruption which occurs as soon as a certain maximum current strength has been attained. The specimens wires were 0.1 mm in diameter and 25 mm in length. The sublimation energy was calculated from the current and voltage oscillograms which had been photographed from the screen of an oscilloscope. An analyse of this oscillogram showed that in the  $\alpha$ -phase ( $0 \leq C \leq 0.03$ ;  $C = H/Pd$ ), the sublimation energy is sharply diminished with increasing hydrogen content ( $dE/dC = 400$  kcal/gram-atom).  $dE/dC$  vanishes when the  $\beta$ -phase appears ( $0.23 \leq C \leq 0.46$ ). Here, the sublimation energy amounts to 56 kcal/gram-atom of Pd. With a further rise of the hydrogen content, the sublimation energy again increases, and it amounts to 69 kcal/gram-atom of Pd at  $C = 0.78$ . According to numerical evaluations, the decrease of sublimation energy in the  $\alpha$ -phase from 100 to 88 kcal cannot be attributed to an increase of the lattice parameters. Furthermore, the  $\beta$ -phase is more stable than the mixed one ( $\alpha + \beta$ ). F. V. Kashin and A. V. Zakharova are thanked for assistance in experiments. TITLE: Occurrence of current flow interruptions and formation of shock waves in rapid heating of metal by electric pulses of high current density

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 31, no. 5, 1961, 557-564

TEXT: The behavior of metals at high temperatures and pressures can be studied by heating the material with current pulses. The maximum temperature obtainable in this way is  $6300^{\circ}\text{C}$ . Further increase of temperature is limited by a momentary interruption of the current flow into the metal, which also stops the input of energy. The authors studied the explosive melting of metals, which is caused by current pulses. The duration of the initial pulse varied from  $2 \cdot 10^{-7}$  to  $1.5 \cdot 10^{-6}$  sec, and the total duration of the experiment did not exceed 4  $\mu\text{sec}$ . The study included the mechanisms of metal heating, of the occurrence of current flow interruptions, and of the formation of shock

Occurrence of...

waves and light flashes of optical emission. Theoretical considerations are based on the assumption that a metal is a system of particles interacting through their Coulomb forces. The mechanism of metal evaporation by current is discussed on a kinetic basis. The occurrence of current interruptions is ascribed to the sharp decrease of binding forces caused by the enlargement of the lattice distance. Thus, the conduction electrons undergo a process that is reverse to the "collectivization" occurring during the condensation of metal vapor. This process is called "decollectivization", and is regarded as the cause of the loss of conductivity and, consequently, of the current interruption. The authors examined the rate of development of current interruptions for a metal into which not more than the sublimation energy was introduced. It could be shown that the sublimation energy is the minimum required for the occurrence of current interruptions. Table 1 contains the minimum values of energy introduced into various metals, at which current interruptions still occur. An investigation of the current drop during a current interruption at different rates of energy supply can give valuable information on such gasdynamic quantities as the velocity of rarefaction waves, the velocity of the "decollectivization" front, etc. Fig. 2 shows oscillo-

Occurrence of...

grams of current (a) and voltage (b) at the wire, as well as light flashes (c). The diagram (d) graphically shows the energy supply in the first phase of explosion of a copper wire at a voltage of 18.5 kw. It is shown that temperature increases with decreasing velocity of rarefaction waves, i.e., higher temperatures are reached in metals in which the velocity of sound is low. Next, the authors investigate the energy released by loading a circuit consisting of the variable parameters  $R(t)$  and  $L(t)$ , which is practically an unknown quantity. Finally, it is shown that the physical parameters of the metals examined have an essential influence on the development of current interruptions (Fig. 5). The absence of current interruptions in tungsten, tantalum, molybdenum, and zirconium, observed in experiments in air, is ascribed to their strong thermionic emission, which causes conduction on the surface of the specimens. For comparison, experiments were made in air and with specimens sealed in glass, which support this opinion (Fig. 6). A. A. Bezrukov and F. V. Kashin are thanked for a number of experiments. There are 6 figures, 1 table, and 9 references: 3 Soviet-bloc and 6 non-Soviet-bloc.

TITLE: Remote anemorhumbograph. Class 42, No. 173993

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 16, 1965, 98-99

TOPIC TAGS: wind direction instrument, wind velocity, wind meter

ABSTRACT: This Author Certificate presents a remote anemorhumbograph containing a wind sensor in the form of a four-bladed propeller fastened to the front part of a drop-shaped hull with an empennage as a wind vane, a tachometer-generator, and two selsyn-detectors (see Fig. 1). To record the average and instantaneous wind velocity on a common scale of the recorder tape, the wind sensor shaft is coupled to the tachometer-generator using bevel gears and to the selsyn-detector through a reductor. The number of revolutions of the wind sensor during a given time interval is transformed into the angular displacement of the selsyn rotor. To record the instantaneous wind velocity as the total velocity profile or as the excess over the average wind velocity, the average wind velocity recorder carriage is provided with a switching pin which lifts the pen with its passage through the average velocity line or limits

TITLE: Wind-parameter sensor. Class 42, No. 180415

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 7, 1966, 81

TOPIC TAGS: meteorologic instrument, wind measuring set; anemometer, telemetry

ABSTRACT: A sensor is described for measuring wind parameters to be used in automatic telemetering of meteorological data. The device includes a wind recorder (airscrew), a streamlined casing with a shaft used like a pressure vane, a windmill pulse rpm converter, a selsyn for sensing wind-direction angles, units for processing mean and maximum wind velocities, and a wind-direction angle converter (see Fig. 1). This device differs in that its pulse converter is connected to the mean velocity data-processing unit, which has computer cells connected to the synchronizing unit and to the memory unit of the set; this arrangement makes it possible for the central part of the set to measure mean wind velocities averaged over one-min intervals and

TITLE: Present status and prospects for development of wind parameter measurements

SOURCE: Vsesoyuznoye nauchnoye meteorologicheskoye soveshchaniye. 1st, Leningrad, 1961. Pribory i metody nablyudenii (Instruments and methods of observation); trudy soveshchaniya, v. 9. Leningrad, Gidrometeoizdat, 1963, 166-181

TOPIC TAGS: meteorology, meteorological instrument, wind, wind parameter, anemorhumbometer, anemorhumbograph, wind direction, wind velocity, anemometer

ABSTRACT: The GUGMS SSSR (Main Administration of the Hydrometeorological Service of the SSSR) is presently developing a set of wind-measurement instruments, including an anemorhumbometer and an anemorhumbograph. The two instruments will have sensing elements in common but the first will measure and the second record the mean and instantaneous wind velocity and its direction. In both instruments the measured wind parameter values are converted to electric pulses. Mean wind velocity is measured by determining the path traveled by an air current during a period of averaging; during this time the wind sensor makes a certain number of revolutions proportional to the length of the path traveled by the flow. The angle of mean wind velocity is transmitted to the control panel by selsyns of the

Card 1/3

ACCESSION NR: AT4033566

anemorhumbometer; the same function is performed in the anemorhumbograph by a servomechanism. The same selsyns are used for transmission of the position angle of the vane in wind direction measurement. The anemorhumbograph differs from other such instruments in that the mean and instantaneous values are recorded on the same tape at the same scale. Wind velocity is recorded in three variants and wind direction in two. The anemorhumbograph recorder has several rates of paper movement. The need for development of printing anemorhumbographs is noted. The Glavnaya geofizicheskaya observatoriya (Main Geophysical Observatory) has proposed a number of devices (Trudy GGO, No. 103, 1960) for averaging registered values by the moving averages method, making it possible to read the mean velocity value for any moment of time. It also is noted that one of the inadequacies of existing wind instruments is that there is no averaging of wind direction; the author has proposed a method and apparatus for solution of this problem, and describes them in this paper. The proposed instrument makes it possible to average wind direction spatially and at the same time smooth individual gusts. Averaging of the wind vector is discussed in detail. It is shown that true mean velocity and true mean direction can be determined only by averaging the wind velocity vector but at the present time wind measurement instruments make it possible to obtain only the mean value of the wind velocity modulus. A method and apparatus developed at the Main Geophysical Observatory for averaging the wind vector is described.

TITLE: Mastering of the Production of Tubes by Atomic Hydrogen Welding

PUBLICATION: Sib. 1959, № 9, pp 621-627 (USA)

ABSTRACT:

In view of some difficulties in piercing tube billets from some alloy steels and a high consumption of metal in subsequent rolling, the production of tubes from such steels by atomic hydrogen welding of strip should be more economical. After investigations of the process by Teplich and the Moscow Tube Works on an industrial plant for the atomic hydrogen welding of tubes was developed. Conditions or viability of welding are on the diameter of electrodes and their holders supplying hydrogen - table 1; the dependence of electrode parameters on the arc on the rate of supply of hydrogen and the distance between the centres of electrodes - figs 3 and 4 respectively. The installation for the production of alloy tube consists of a modified tube fragmenter of type 10 - 60, six arcs automatic welding unit, a control panel, welding transformer and a storage tank.

Card 1/2

gas and water condensate (fig 5). The welding unit - fig 6, scheme for automatic control - fig 7. Technical conditions for steels 1Kh13N, Kh13N13, 20Kh13N13, 10Kh13N13 - Table 2; results of testing of welded joints - Table 3; macro and microstructure of welded joints - figs 3 and 9 respectively. The results of testing of the welded tubes indicated that their properties correspond to standards for stainless steel tubes (GOST).

There are 9 figures and 3 tables.

TITLE: Universal device for neutron-diffraction structure analysis

SOURCE: Pribory i tekhnika eksperimenta, no. 2, 1964, 43-46

TOPIC TAGS: neutron diffraction, structural analysis, neutron diffraction analysis,  
diffractometer, neutron collimator, neutron monochromatorABSTRACT: A new device combining the features of those described by Borst  
and Sailor (Rev. Scient. Instrum., 1953, 24, 141) and Wallan and Kochler  
(Phys. Rev., 1955, 100, 545) consists of three mechanically independent compo-  
nents: a neutron collimator 1 (see Enclosure 1), a crystal monochromator 2, and  
a diffractometer. The collimator is formed by Ni50-alloy 0.1-mm sheets with  
2-mm gaps. The monochromator includes a Pb 10x80x200-mm plate cut from a

Card 1/3

ACCESSION NR: AP4033104

single crystal and fastened to a goniometer. The diffractometer can be adjusted to any wavelength from 1.5 Å to the "white" radiation. Proportional counters filled with BF<sub>3</sub>, at 400 torr with up to 86% B<sup>10</sup> are used for neutron detection. Three neutron-diffraction curves are shown; design details are supplied. "The assembling and testing of the first laboratory model of the device were carried out by V. I. Goman'kov, N. V. Grin'kin, S. A. Vyazemskiy, D. F. Litvin, A. A. Loshmanov, and B. G. Lyashchenko." Investigation of the Electrostatic Emission of Electrons  
(EEE) From a Wolframite Emitter Under Impulse ConditionsPERIODICAL: Izvestiya Akademii nauk Uzbekskoy SSR, Seriya fiziko-matema-  
ticheskikh nauk, 1959, Nr 6, pp 72 - 77 (USSR)

ABSTRACT:

The authors consider impulse measurements of the electro-  
static emission of electrons and compare their method and  
results with the papers of Dyke and others [Ref 3,4,6,7]  
and of Barbour and Dolan [Ref 5]. In these papers it isassumed that the emission current is  $i_e = \frac{u_2}{R_o}$ , where  $u_2$ is the voltage drop on the resistance  $R_o$  obtained from the  
oscillogram. The authors show that this method for cal-  
culating  $i_e$  can cause essential errors. The relation $u_2 = i_e R_o$  holds with high exactness only at the end of the  
impulse, if its duration is sufficiently long. Accordingly

TITLE: Emission parameters of tantalum and molybdenum single crystals A

SOURCE: Fizika tverdogo tela, v. 8, no. 4, 1966, 1140-1146

TOPIC TAGS: tantalum, molybdenum, crystal, electron emission, work function, crystal lattice structure

70  
B

ABSTRACT: This is a continuation of earlier work (FTT v. 7, 3759, 1965 and others) devoted to the work function of electrons from different faces of single crystals of tungsten and molybdenum. The present investigation reports similar measurements with large crystals of tantalum, accompanied by new measurements on molybdenum and comparing the results and refining earlier data. Most measurements were made in a cylindrical system of electrodes (Fig. 1), although some were made with a flat system of electrodes used in the earlier experiments. The measurements were made by the Richardson method. The values obtained for the work functions of molybdenum are  $\varphi_{110} = 5.00 \pm 0.05$ ,  $\varphi_{112} = 4.55 \pm 0.05$ ,  $\varphi_{100} = 4.40 \pm 0.02$ , and  $\varphi_{111} = 4.10 \pm 0.02$  ev. The values for tantalum were  $\varphi_{110} = 4.80 \pm 0.02$ ,  $\varphi_{100} = 4.15 \pm 0.02$ , and  $\varphi_{111} = 4.00 \pm 0.02$  ev. The results for tungsten, molybdenum, and tantalum are tabulated and compared, and some of the differences are discussed. It is concluded that for metals with a body-centered cubic lattice the average work function is closest to that in the [100] direction. The difference between the maximum and the minimum work function is

AUTHORS: Gofman, I. I., Protopopov, O. D., Shuppe, G. N.TITLE: Investigation of the Electrostatic Electron Emission From  
a Tungsten Emitter in Pulsed Operating ConditionsPERIODICAL: Fizika tverdogo tela, 1960, Vol. 2, No. 6, pp. 1323-1327

TEXT: The pulsed electrostatic electron emission from pure tungsten emitters has already repeatedly been investigated for the purpose of verifying the quantum-mechanical theory of this emission at high current densities. However, the peculiarities occurring in pulsed operation are not sufficiently considered, so that some of the data were found to be faulty. The present paper contains a detailed discussion of the measuring methods, results of the authors' own measurements, and a summary of results. The square pulses used in the so-called pulse measuring method have a duration of  $10^{-6}$  sec; such a pulse is used for the purpose of determining each individual point of the current-voltage characteristic. Fig. 1 shows a general wiring diagram such as is used

for such measurements. According to the method described measurements were carried out both statically (range of low amperages) and by the pulse method (range of high amperages). The experiments were carried out in projectors with a luminescence screen for the purpose of observing the emission picture also in lamps with a pure metallic anode. The pressure in the measurements was of the order of  $10^{-10}$  torr. A specially constructed impulse generator was used, which maintained the voltage on the pulse-height plateau ( $1-2 \mu\text{sec}$ ) constant with an accuracy of 0.1%. A two-ray oscilloscope was used for pulse-recording. Some ten characteristics were recorded; one of them is shown in Fig. 3. Fig. 4 contains a number of oscillograms showing points A - E of the current-voltage characteristic. Fig. 5 shows a dark photograph of the emitter in the electron microscope ( $1:10^7$ ). A qualitative comparison between the experimental results and the electrostatic electron emission equations is carried out, a) for the case of a square barrier, b) under the assumption of a barrier rounded off by the forces of the electric image, and c) corresponding to the many-electron problem with the

TITLE: Field emission from silicon

SOURCE: AN UzSSR. Izvestiya. Seriya fiziko-matematicheskikh nauk,  
no. 4, 1964, 62-72

TOPIC TAGS: emission, electron emission, electrostatic emission,  
electrostatic electron emission, silicon emitter, silicon emission  
pattern

ABSTRACT: The electrostatic emission patterns of silicon needle  
cathodes were obtained by the field desorption method (Cooper, E. C.,  
Muller, E. W., Re. Sci. Instr. 29, 1958, 309), which makes it possible  
to discount the effect of boron contaminants adsorbed from glass con-  
tainers. The cathode was made in the form of a needle integral with  
a 1 x 4.8 x 15 mm plate. The vacuum in the chamber was brought down  
to  $10^{-10}$  mm Hg. The cathode was heated intermittently prior to mea-  
surements to temperatures of 950—1350K. The field desorption was  
then applied and the change of the emission pattern observed during

Cord.1/3.

18330-65  
ACCESSION NR: AP5000469

the desorption process. A temperature of about 1350K is considered necessary for effective degassing before desorption. The vacuum should be considerably below the  $10^{-8}$  mm Hg level. The reverse potential necessary to start the desorption was found to be about 5 times higher than that needed to obtain an emission of the order of  $10^{-7}$  amp. The voltage-current characteristics for variously oriented n- and p-type single crystals with specific resistivities of 0.05 to 72 ohm-cm were plotted and the dependence found to be linear within the current range from  $5 \times 10^{-11}$  to  $1 \times 10^{-5}$  amp. Pulse measurements up to  $7 \times 10^{-2}$  amp resulted in a departure from linearity toward the higher currents. The pulsed current exceeded the stationary value at the same voltage by at least an order of magnitude. None of the voltage-current graphs obtained in the experiments displayed the expected "bend" due to the penetration of the field into the region of the "typical" semiconductor. On the contrary, the curves tended to bend in the opposite direction! This phenomenon is explained tentatively by the nonequilibrium condition of the emission at given field strengths. In general, the relationship should become linear in the case of strong surface degeneration. If it is assumed that degeneration does not occur, the current rise most probably results from overheating of the electron gas. Orig.

TITLE: Selecting the parameters of crank presses for die pressing

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, no. 2, 1963, 1 - 7

TEXT: The authors point out that, since the existing press designs used in die pressing show a number of deficiencies, plants and institutes in the Soviet Union and abroad have been trying for some years to design die-forging presses particularly adapted to die pressing. In this connection they mention press designs developed by Messrs. Massey and an automatic 1,000 ton press designed and built by the Voronezh TMP Plant according to orders of the Kuybyshev "Avtotraktorodetal" Plant. The TsEKM provided for the development of a range of crank presses of from 400 to 4,000 tons capacity, while the ENIKMASH together with MAMI suggested the basic parameters of these presses in 1961. Engineers S. A. Ryaskov and Yu. I. Lubyanskiy participated in this work. To determine the main press parameters, a great number of components were studied that are pro-

Selecting the parameters of...

duced by plants of the automotive, agricultural machine-building, machine-tool, shipbuilding and aircraft industries, of which some 100 types and sizes were chosen that could be expediently produced by die pressing. It was found that the number of transitions, depending on the configuration and size of the forgings, very often does not exceed three (upsetting, pressing and final die pressing). The authors give a detailed description of the rating of the main press parameters suggested, present appropriate formulae, graphs and tables, and point out that these parameters have been approved by a number of plants. There are 5 figures and 3 tables.

TITLE: Press forging in sectional dies

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, no.12, 1962, 3-8.

TEXT: ENIKMASH and the Moskovskiy avtomekhanicheskiy institut (Moscow Automechanical Institute) jointly studied the sectional-die forging process by forging two types of automotive universal joints. The universal joint was chosen because it is a typical automobile part with long protrusions that can be economically fabricated by the sectional-die forging method. The article gives a detailed description of the two experimental dies sets, observations of metal flow in the die and the transition radii, gaps between the punch and the die container, and the forging outline giving proper filling of the die without burrs. Engineering recommendations are given. Studies have yet to be continued to find the necessary technological data for the forging of parts other than universal joints. The recommendations concern the outline of the forging, the use of one-stage and two-stage forging for different forgings, the types of special presses to be developed. Reference

Sponsoring Agency: Ministerstvo vyshego obrazovaniya SSSR. Professor I.M. Naumov. Doctor of Technical Sciences. Professor I.M. Naumov. Publishing Ed.: O.M. Doboleva; Tech. Ed.: V.D. Z. Vinogradov. Magazine Ed. for Literature on Heavy Machine Building (Pashkov); S. Ya. Golovin, Engineer.

Purpose: The book is intended for engineering and scientific personnel of plant laboratories, stamping and forging shops. It can also be used by students.

Content: The authors of the eight articles in this collection discuss methods of pressings, analysis, speed and power efficiency, problems in pressing and forging, rates of deformation, and other problems conducted by the Department of Metal Forming of the Moscow Institute of Metal Forming of the Moscow Automation and Mechanization Institute. References appear at the end of each article.

Author(s): I.M. Naumov. Investigation into the properties of sheet metal. Investigation into the service of upsetting type stock.

The article is divided into three sections: problems of stress, problems of stability, and experimental results. The article analyzes the process of deformation of stock in the press and derives formulas for press force.

Olsor, I. M. Candidate of Technical Sciences. Experimental investigation of the formation of flow lines in cold stamped and drawn body sections of Automobiles. The article covers the surface layer of sheets, formation of flow lines as a result of elongation stress, flow lines in deep drawing, and flow lines in cold-worked parts.

Tolokon, I. S. Engineer. Aspects of Rapid Heating of Pressing Blanks. Aspects of Rapid Heating of Pressing Blanks. The author discusses and evaluates five methods of heating: rapid heating in a flame furnace, induction heating, arc-furnace heating, heating in an electric arc, and heating in solid glass. No definite conclusions as to economic advantages of any of these methods are drawn.

AUTHOR: Protopopov, O. V.

TITLE: The Development of the Technology of Upsetting of Pipes on  
Horizontal Forging Presses (Razrabotka tekhnologii vysadki trub na  
gorizontal'nokovochnykh mashinakh)

PERIODICAL: Tekhnol. avtomobilestroyeniya, 1958, Nr 4, pp 23-35

ABSTRACT: The author derives formulas for the determination of the stresses of upsetting ( $U$ ) of pipes by analyzing force systems operating during  $U$  of pipe blanks ( $B$ ) at an instant when the entire hollow of the die (in which the metal is deformed in such a manner that the outer diameter is increased and the inner diameter is reduced) is filled with metal. A computation of the number and degree of intensity of successive  $U$  steps is presented on the basis of a study of the ability of tubular rods to resist buckling while in a plastic state. The results of the theoretical investigation were compared with shop and experimental data. During operations of  $U$  of pipes in a horizontal forging press in which the external diameter ( $D$ ) of the pipe is kept constant, the degree of thickening of the wall is not limited by its buckling behavior

Card 1/2

SOV/137-59-3-6881

## The Development of the Technology of Upsetting of Pipes (cont.)

but rather by the rigidity of the clamping mechanisms and by the length of the portion being deformed. Over a wide range of lengths (up to  $l_o = 3D_o$ ) the thickness of the wall may be increased by 1.25 times by increasing the outer D without altering the inner D. An increase of 1.5 times is possible only in the case of short specimens ( $l_o < 0.5 D_o$ ). The correctness of the formula derived for the determination of stresses at the instant when the entire hollow of the die is filled with metal is corroborated by oscillograms of the force conditions prevailing during operations of U of pipes involving an increase in the outer D of the original B's. Theoretical and experimental data were employed in plotting the permissible increase in wall thickness as a function of  $l_o/D_o$  for the case of U of B's under the following conditions: Constant outer D; constant inner D, and a combination of these two cases. The order of computing the number and the degree of intensity of successive steps in U of hollow forgings of tubular B's is presented and an example illustrating the computation is examined.

domstvennyy respublikanskiy nauchno-tekhnicheskiy sbornik, 1966. Akustika i ul'trazvuk  
(Acoustics and ultrasonics), no. 1, 59-65

TOPIC TAGS: photoelasticity, pressure measurement, ultrasonic vibration, electric  
field, electromagnetic wave dispersion, stress analysis

ABSTRACT: Analytical and experimental photoelastic techniques for studying variable  
pressures induced by ultrasonic oscillations are described. A plane-parallel photo-  
elastic element having monochromatic light passing through its face was analyzed under  
static and dynamic stress applications. Equations are given for oscillating electric  
fields and static loading and a polarization ellipse is constructed. These equations  
are applied to the case of variable loading for which the amplitude of oscillation is  
given by

$$S = E_0^2 \sin^2 2\alpha \sin^2 \left( \frac{\pi}{\lambda} z l P_0 \sin \Omega t \right).$$

Card 1/2

L 03888-67

ACC NR: AF6026366

where  $P = P_0 \sin \Omega t$  is the variable pressure,  $\lambda$  is the monochromatic wavelength,  $\alpha$  is the angle between the polarization plane and the direction perpendicular to the face,  $l$  is the thickness of the photoelastic material,  $\gamma$  is a material constant, and  $E_0$  is the maximum amplitude of the electric wave. This equation applies only to the case where

$$\frac{\pi}{\lambda} \alpha l P_0 < 1.58,$$

since, in this case the maximum pressure corresponds to the maximum intensity. For glass, this condition is almost always fulfilled. The maximum sensitivity occurs when  $\alpha = \pi/4$ :

$$S = E_0^2 \sin^2 \left( \frac{\pi}{\lambda} \alpha l P_0 \sin \Omega t \right).$$

An experimental arrangement used for obtaining calibration curves is shown. In these curves, the oscilloscope voltage is given as a function of ultrasonic pressure for a photoelastic glass of 2 mm thickness and 32 mm width. The average pickup sensitivity at a given frequency depended on the alternating pressure: at a frequency of 20 kilocycles/sec, it was  $10^{-6}$  mv/bar. Orig. art. has: 4 figures, 18 formulas.

TITLE:

Calibration of thermoelectric meters of ultrasonic  
intensity

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika,  
no. 12, 1962, 12, abstract 12-5-23 e (Nauchn. zap. O-  
detsk. politekhn. in-t, v. 37, 1962, 54-59)

TEXT: The problem of the calibration of thermoacoustic pickups is  
considered. The authors suggest that the intensity distribution be  
determined in relative units at a certain distance from the transdu-  
cer by means of a coordinate-type apparatus, using the topographi-  
cal-survey method. The obtained energy values should be added to-  
gether and equated to the calorimeter. The proportionality factor will then be the  
e.g. by a calorimeter. The energy measured by some absolute method,  
sensitivity of the temperature detector. Data are given on the method  
of calibrating pickups in the form of differential thermocouples

TITLE: Interference-type ultrasomic energy absorber

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika,  
no. 12, 1962, 12, abstract 12-5-24 d (Nauchn. zap.  
Odessk. politekhn. in-t, v. 37, 1962, 9-16)

TEXT: The problem of two-layer absorber intended for wide-band measuring probes is considered theoretically. Formulas are obtained that make it possible to select both the materials and thickness of the intermediate layer for an interference-type absorber permitting a travelling wave to be set up in the waveguide. An example is given of calculations for an absorber for a nickel waveguide where glycerine is used as the intermediate layer. It is pointed out that in this case best results are obtained with cork and plaster. *[Abstracter's note: Complete translation.]* VB

TITLE: Interference ultrasonic energy absorber

PERIODICAL: Referativnyy zhurnal, Fizika, no. 9, 1962, 36, abstract 90266  
("Nauchn. zap. Odessk. politekhn. in-t", 1962, v. 37, 9 - 16)

TEXT: For the purpose of eliminating undesirable reflected waves in a waveguide during the production of a wide band probe, the use of an interference absorber is proposed. A theoretical analysis is made of the problem of wave damping for the case of superposition of a direct wave and a series of reflected waves in a two-layer absorber design. For some particular cases the optimum thickness of the layer between the waveguide and the absorbing material is calculated and the latter is selected. The calculations show that for the case when nickel is used for the waveguide and glycerin as intermediate medium, cork and gypsum are the most suitable materials to obtain an operational band up to 100 kilocycles.

UNION/GOVT Economic Measures 4102. Jan 1947  
"Economic Reserves in Capital Construction," S.  
Protopopov, 41 pp

"Sov Finansy" Vol VIII, No 1

Analysis of construction work being carried on by various ministries and comparison of construction costs. Analysis of factors which contribute to high costs of construction. One criticism relates to starting too many projects at same time and not completing them so that they can be put into use, e.g., the Bokhitstroy enterprise is working on 147 objectives at the same time. Plan for capital work for first half of 1946 was fulfilled by 98.6% but plan for putting projects into operation has only been 38.1% completed. LC
